Trends in suicide and suicide risk factors among high school students in New York City. Trends in suicides and suicide risk factors among adolescents were examined using data from New York City public high schools. The most recent year for which data were available was 1998. Suicide and suicide risk factors were compared using statistical analyses of data from 1997 to 1998 and from 1991 to 1996. During 1998, there was a decline in suicide rates by age among all adolescents and among girls. The decline was most marked among younger students. There was a decline in suicide rates in high schools, and the decline was consistent across race and ethnicity. Significant declines were also observed for the number of students who reported feeling sad and hopeless. However, significant increases were observed for the number of students who reported feelings of anger, conflict, and fear. A statistically significant increase was also observed for the percentage of students who reported feeling depressed, sad, or hopeless at school. A statistically significant decrease in the percentage of students who reported using alcohol or other drugs at school was observed. These changes in trends were observed in students of all ages, with the largest declines occurring among younger adolescents. These findings suggest that suicide prevention strategies that address suicide risk factors among students of all ages are needed.

Shade-tolerant and crown-specific ecophysiology of a New Zealand tree, *Rhynchospermum japonicum* (Ulmaceae), reveals niche partitioning between branches and trunks. *Rhynchospermum japonicum* is a tree species native to southern New Zealand, where its wood is used for building houses and boats. Shading within the canopy of a natural forest has a detrimental effect on growth, and there is little information on how shade affects the ecophysiology of plants in this tree. We therefore compared leaf gas exchange and plant water potential and conductivity, along with
